

Short Communication**Response of Dipteran larvae exposed to acute doses of different heavy metals and its impact on aquatic environment.****ABSTRACT**

Industrial effluents contain heavy metals, which are the main source of water pollution due to their bioaccumulation and magnification in different trophic level. The aim of this work to estimate LC<sub>50</sub> of Pb, Cd and Hg in *Chironomus striatapennis* which is a primary consumer of aquatic ecosystem. Fourth instars were collected from breeding aquarium reared under laboratory conditions and exposed for 96 hours to different doses of Pb, Cd and Hg for static bioassay of LC<sub>50</sub>. Ten fourth instar larvae were placed in 100 ml beaker with 50 ml of each test solution. Each concentration consists of five trials. A control was also maintained wherein organisms were exposed to distilled water. Larvae were not fed during the toxicity tests. All beakers were free from tube forming materials. Data were subjected to probit analysis. Result showed that sensitivity of larvae was Hg > Cd > Pb and Chi square for Heterogeneity were also found significant in all three metals. *C. striatapennis* showed noticeable response in LC<sub>50</sub> study and sensitive to low doses of heavy metals. Several secondary consumers have preferred this larva as their food. So unplanned industrialization may increase the level of heavy metals in the aquatic ecosystem which will accumulate slowly but definitely in different trophic level and at the same time unusual death of these larvae may indirectly change the equilibrium of the aquatic ecosystem.

Key Words: LC<sub>50</sub>, Mercury, Lead, Cadmium, *Chironomus*.

## 28 INTRODUCTION

29 Industrialization means a change in the technology to produce goods and service as well as  
30 an engine of growth in developing countries [1,2]. It is known that there exist darkness under  
31 the lamp, industrialisation also leaving behind serious environmental issues like water  
32 pollution[3]. Both fresh and marine water are polluting everyday by untreated or improperly  
33 treated industrial wastewater. Over 80% of the world's wastewater and over 95% in some  
34 least developed countries is released to the environment without treatment [4]. It is estimated  
35 that in India 13,500 million litres per day industrial wastewater is generated from urban cities  
36 and discharging nearby aquatic bodies with or without treating the waste water [5]. Industrial  
37 wastes from different industries, such as mining operations, metal plating, radiator  
38 manufacturing, tanneries, smelting and alloy industries, storage battery industries are the  
39 significant source of heavy metals [6]. Among the heavy metals, Cd, Pb and Hg, are  
40 considered as most hazardous water pollutants [7,8]. Due to their high solubility in water,  
41 heavy metals could be absorbed by living organisms once they enter the aquatic food chain  
42 [9]. Benthic primary consumer like chironomid larvae (Order Diptera, Family Chironomidae)  
43 are continuously exposed to such environment, and may contribute to the accumulation and  
44 bio transfer of these heavy metals to upper trophic level and considered as good biological  
45 indicator of aquatic environment degradation [10,11,12].*Chironomus striatapennis* was  
46 found highly sensitive when exposed to different doses of Arsenic salt [13].  $LC_{50}$  is a  
47 statistical parameter which illustrates a complete picture of mortality in a population and also  
48 organism's tolerance to a particular xenobiotic [14]. The objective of the study is to  
49 determine the  $LC_{50}$  of Pb, Cd and Hg in *Chironomus striatapennis* to find how this  
50 macroorganism is responding to these heavy metals. This in turn provide information  
51 regarding the level of these metals in the industrial effluents which will not vulnerable for  
52 this primary consumer.

## 53 MATERIAL AND METHODS

### 54 Collection of Chironomid larvae

55 Fourth instar larvae of *Chironomous striatapennis* were collected from fresh water pond  
56 locating at Kanchrapara (22\_56018.664800N, 88\_28010.034400E) district North Twenty  
57 four Parganas, West Bengal, India and placed in aerated plastic bags and transported to the  
58 laboratory. Larvae of chironomid reared under laboratory conditions by using the breeding  
59 aquarium which was filled to a depth of approximately 20 cm with pond water and given fish  
60 flakes for food [15]. This was the source of all test organisms. Atomic absorption  
61 spectrophotometry was done to confirm that larvae were not contaminated with the Lead  
62 (Pb), Mercury (Hg) and Cadmium (Cd).

### 63 Toxicity Test of Heavy metals

64 For contamination, stock of  $1\text{ mg l}^{-1}$  concentration was prepared initially with Cadmium  
65 acetate (SRL, 99% purity), Lead acetate (SRL, 99% purity) and Mercuric chloride (SRL,  
66 98% purity) in double distilled water and kept for twenty four hours. Test solution of  
67 different concentrations were prepared from that stock, through a series of dilution. Initially a  
68 series of tests were conducted in concentrations ranged between  $0.0005\text{ mg l}^{-1}$  and  $1\text{ mg l}^{-1}$ ,  
69 where test organisms been exposed for 96 hours. Finally for Cd, concentrations of  $0.001\text{ mg l}^{-1}$   
70  $^1(\text{d1})$ ,  $0.003\text{ mg l}^{-1}(\text{d2})$ ,  $0.007\text{ mg l}^{-1}(\text{d3})$ ,  $0.015\text{ mg l}^{-1}(\text{d4})$ ,  $0.03\text{ mg l}^{-1}(\text{d5})$  and  $0.062\text{ mg l}^{-1}(\text{d6})$ ;  
71 for Hg,  $0.0005\text{ mg l}^{-1}(\text{d1})$ ,  $0.001\text{ mg l}^{-1}(\text{d2})$ ,  $0.003\text{ mg l}^{-1}(\text{d3})$ ,  $0.007\text{ mg l}^{-1}(\text{d4})$ ,  $0.015\text{ mg l}^{-1}(\text{d5})$   
72 and  $0.031\text{ mg l}^{-1}(\text{d6})$ , and for Pb,  $0.003\text{ mg l}^{-1}(\text{d1})$ ,  $0.007\text{ mg l}^{-1}(\text{d2})$ ,  $0.015\text{ mg l}^{-1}(\text{d3})$ ,  $0.031\text{ mg l}^{-1}$   
73  $^1(\text{d4})$ ,  $0.062\text{ mg l}^{-1}(\text{d5})$  and  $0.125\text{ mg l}^{-1}(\text{d6})$  were considered for the experiment. Tenfourth  
74 instar larvae were placed in 100 ml beaker with 50 ml of each test solution. Each  
75 concentration consists of five trials. A control was also maintained wherein organisms were  
76 exposed to distilled water. Larvae were not fed during the toxicity test. All beakers were free  
77 from tube forming materials. The criterion for death is immobility and/or lack of reaction to

78 mechanical stimulus. After 96 hours, recorded data were subjected to probit analyses[16] by  
 79 using Probit Programme Version 1.5.

80 **RESULTS**

81 LC<sub>50</sub> and LC<sub>90</sub> values and 95% confidence limit for Hg, Cd and Pb in the fourth instar of  
 82 *Chironomus striatapennis* are presented in Table 1. The result revealed that sensitivity of  
 83 larvae was Hg>Cd>Pb. Chi-square for Heterogeneity were also found significant in all three  
 84 metals in compare to tabulated value of Chi-square (7.815, P<0.05). Percentage of mortality  
 85 of larvae exposed to three heavy metals is presented in Fig.1.

86 **Table 1: LC<sub>50</sub> Confidence Limit of *C. striatapennis***

	Mercury	Cadmium	Lead
<b>Exposer Period</b>	96 Hour	96 Hour	96 Hour
<b>LC<sub>50</sub> mg l<sup>-1</sup></b>	0.001	0.003	0.007
<b>LC<sub>90</sub> mg l<sup>-1</sup></b>	0.010	0.012	0.104
<b>95% Confidence</b>	<b>Lower Limit: 0.000</b>	<b>Lower Limit: 0.000</b>	<b>Lower Limit: 0.000</b>
<b>Limit for LC<sub>50</sub></b>	<b>Upper Limit: 0.003</b>	<b>Upper Limit: 0.005</b>	<b>Upper Limit: 0.019</b>

92 **DISCUSSION**

93 Mercury, a prevalent toxicant is available in the environment due to anthropogenic activity as  
 94 well as natural sources. Present study revealed that Chironomids were more susceptible to Hg

95 than other two heavy metals and observed  $LC_{50}$  exposed to Hg was  $0.001 \text{ mg l}^{-1}$ , which was  
96 same as human permissible limit ( $0.001 \text{ mg l}^{-1}$ ) of BIS [17] and less than acceptable limit in  
97 industrial effluent ( $0.01 \text{ mg l}^{-1}$ ) [18], but in industrial effluent this metal may be available in more  
98 high concentration [19]. Mercury reduces the growth and decreases the locomotion activity  
99 which leads to an increase in the probability of mortality rate of the larvae [20]. Moreover, an increase  
100 in Hg concentration decreases the survival rate of this larva as was observed in *Eriocheir*  
101 *sinensis* [21].

102 The study revealed that *C. striatopennis* was more susceptible to Cd than Pb and  $LC_{50}$  of  
103 these three heavy metals showed that lead is least toxic for this insect. Toxic effects of  
104 cadmium reduced the uptake of essential metals, specifically Calcium (Ca) ion channels due to  
105 their similarity of size and charge which can disrupt the normal physiological actions of Ca  
106 ion. Though *Chironomus* contains Metallothionein (MT), a metal binding protein (MBP),  
107 having high cysteine content with numerous thiol groups, which may help cellular tolerance  
108 to Cd through high affinity sequestration of the toxic metal by MT [22]. In spite of that,  
109 a severe amount of cadmium may increase the lethality of this organism. Pb was found less toxic  
110 but it also has a similar kind of effect to prevent or imitate the action of Ca ion of Calcium  
111 dependent or allied processes [23]. Moreover, Pb accumulation by this larvae is higher than  
112 other heavy metals due to the presence of MBP which may cause bio-magnification of this  
113 heavy metal in the food chain [24].

114 Our study revealed that the concentration of these metals ( $LC_{50}$ ) used in this experiment,  
115 though below the human permissible limit but not suitable for the survival of the larvae of  
116 this insect. The maximum acceptable limit for Pb and Cd in industrial effluents are  $0.1 \text{ mg/l}$   
117 and  $0.01 \text{ mg/l}$  respectively [25].  $LC_{50}$  was found less than such acceptable limit. Whereas,  
118  $LC_{90}$  for this insect was recorded for Pb ( $0.10 \text{ mg l}^{-1}$ ) and Cd ( $0.012 \text{ mg l}^{-1}$ ) which were similar  
119 to the acceptable limit in the industrial effluents.

120 *Chironomus* have antioxidant defense system, contains antioxidant enzymes like superoxide  
121 dismutase, catalase and glutathione peroxidase. Level of these enzymes decreased with the  
122 increase in stress situation like increasing concentration of heavy metals in aquatic  
123 environment and larvae died due to toxicity of the metals[26]. Chironomids are macrobenthos  
124 and are the primary consumer of the aquatic food chain[27]. Due to unscrupulous industrial  
125 development in the developing countries, there are increased in the industrial effluents  
126 containing heavy metals like Hg, Cd and Pb which ultimately reach the fresh water sources of  
127 those areas. The bioaccumulation of these metals in aquatic organisms is dangerous not only  
128 for their own survival and biology, but also for humans because of the possible passage of  
129 contaminant through the food chain [28].

130 Though there is no noticeable changes are found in higher vertebrates like fish in those  
131 aquatic ecosystem, but our LC<sub>50</sub> results indicated that *C. striatapennis* was highly sensitive to  
132 low doses of heavy metals. Several secondary consumers consider chironomids as there food.  
133 So heavy metal pollution may indirectly distorting the equilibrium of the aquatic ecosystem.  
134 This study provides information for industries to release effluents after proper treatment so  
135 that level of these heavy metals should below the effective level. That is essential for the  
136 sustainable development and to stop the biodiversity loss of the ecosystem.

### 137 **CONCLUSION**

138 LC<sub>50</sub> assay revealed that larvae of *Chironomus striatapennis* was more sensitive to Hg than  
139 Cd and Pb respectively. It was also observed that LC<sub>50</sub> values were less than standard  
140 permissible limit of these heavy metals. As this larvae is preferred by different secondary  
141 consumers, so unplanned industrialization may increase the level of heavy metals in the  
142 aquatic ecosystem which will accumulate slowly but definitely in different trophic levels and  
143 at the same time unusual death of these larvae may indirectly change the equilibrium of the  
144 aquatic ecosystem.
