2 **A retrospective study to analyze the efficacy of**

3 **ceftriaxone+sulbactam+EDTA combination for**

4 **complicated urinary tract infections in diabetic**

5 **patients.**

6

7 **Abstract**

8 **Objective**

9 In general, infectious diseases are more frequent and/or serious in patients with  
10 diabetes mellitus, complicated further by antimicrobial resistance which potentially increases  
11 their morbi-mortality. The objective of this study was to determine the clinical utility of CSE-  
12 1034 (Ceftriaxone+Sulbactam+EDTA) in diabetic patients with complicated urinary tract  
13 infections (cUTIs).

14 **Methods**

15 Diabetic patients with cUTIs who received CSE-1034 as empiric therapy were  
16 screened and further analyzed. CSE-1034 therapy was started empirically in all these  
17 subjects and continued or discontinued based on culture susceptibility profile and clinical  
18 outcome. The statistical analysis was performed using Chi-square test.

19 **Results**

20 Out of 85 patients admitted for cUTI, 38 patients met our inclusion criteria and were  
21 included in this study. *E. coli* was the predominant pathogen isolated followed by *K.*  
22 *pneumoniae*. In vitro susceptibility testing has shown no susceptibility of baseline pathogens  
23 to levofloxacin, gentamicin, ceftriaxone, cefepime, cefazolin, 23.6% to pip-taz, 18.4-23.6%  
24 to beta-lactambeta-lactam inhibitor (BL/BLI) combinations, 63.1% to meropenem and 100%  
25 to CSE-1034. 92.1% of the patients were cured with CSE-1034 empiric therapy and 7.9%  
26 with alternate meropenem therapy.

## 27 **Conclusion**

28 From this study, it can be suggested that CSE-1034 alone appears to be effective drug  
29 for the treatment of multi-drug resistant cUTI in diabetic patients and can serve as effective  
30 alternate to meropenem and replacement for BL/BLI combinations.

31

32 **Key words: Multi drug resistance; Extended Spectrum Beta-Lactamase; Metallo- $\beta$ -**

34

## 35 **Introduction**

36 Type 2 Diabetes mellitus (DM) is a heterogeneous group of disorders resulting from  
37 impaired insulin secretion or action leading to elevated levels of glucose. Other than the  
38 classical complications associated with DM, other outcomes include altered immune  
39 responses including impaired humoral immunity, decreased neutrophil action and reduced  
40 response of T cells <sup>1 2 3 4</sup>. Consequently, DM raises the risk of contracting infections,  
41 including the most common ones as well as those that almost only affect people with DM <sup>2 5</sup>.  
42 In addition to the associated repercussions, such infections may lead to serious manifestations  
43 and/or trigger DM complications.

44 Urinary tract is one of the most common infection site in individuals with DM. [25–  
45 27] Asymptomatic bacteriuria and symptomatic urinary tract infections (UTIs) are both  
46 reported to be more frequent in patients with type 2 diabetes than in the general population <sup>6</sup>  
47 <sup>7</sup>. Available evidences also suggest that type 2 diabetes increases susceptibility to serious  
48 complications of UTI, including emphysematous conditions of the bladder or kidney, renal  
49 abscess, and renal papillary necrosis <sup>8 9 10</sup>. The different mechanisms that may contribute to  
50 the higher frequency of UTI and related complications among diabetic patients include  
51 impaired immune system, primarily diabetic nephropathy and cystopathy, recurrent vaginitis,  
52 incomplete bladder emptying, poor glycemic control, and higher glucose levels in the urine  
53 which may facilitate the growth of pathogenic organisms <sup>5 7 8</sup>.

54 Given the increasing incidence of type 2 diabetes mellitus worldwide in recent years  
55 projected to be 380 million cases in 2025 and the clinical link between diabetic status and  
56 UTI risk and severity, a substantial burden of UTIs is going to increase <sup>11</sup>. Moreover, the high  
57 rates of antibiotic prescription in these patients, including broad-spectrum antibiotics, may

58 further induce the development of multi-drug resistant urinary pathogens<sup>1213</sup>. Ceftriaxone  
59 fortified with sulbactam and antibiotic resistance breaker “EDTA” (CSE-1034) is a newly  
60 approved antibiotic adjuvant entity for the treatment of infections caused by Extended  
61 Spectrum Beta-Lactamase/Metallo- $\beta$ -lactamase (ESBL/MBL) producing gram negative  
62 pathogens<sup>14 15 16 17</sup>. In this study, we discuss a series of 25 diabetic patients suffering from  
63 cUTI and treated successfully with CSE-1034.

## 64 **Material and Methods**

### 65 **Study population**

66 The case history sheets of all the patients admitted to the hospital for treatment of  
67 bacterial infections between June 2016 to June 2017 were analyzed. Adult diabetic patients  
68 with age of  $\geq 18$  years and treated for cUTI were included in this retrospective study. The  
69 criteria for patient selection were 1) Diabetic patients diagnosed with cUTI based on various  
70 lab parameters and relevant signs and symptoms 2) Isolation of gram-negative pathogen at  
71 the base-line 3) Patients who received CSE-1034 at least for a period of  $\geq 48$ h 3) Patients who  
72 received CSE-1034 as 2nd line of therapy.

73 The cUTI included had at least three of the following signs and symptoms: fever  
74 ( $>38^{\circ}\text{C}$ ) and chills, increased frequency and urgency of urination, dysuria, costo-vertebral  
75 angle tenderness or abdominal tenderness, flank pain, or the presence of pyuria and colony  
76 count of  $\geq 10^5$ CFU/ml was must.

### 77 **Patient analysis, antibiotic usage and outcomes**

78 Information regarding demographic and baseline characters including gender, age,  
79 infection type and source, pathogen isolated, co-morbidities, antibiotic therapy, dose and  
80 duration for all the patients was retrieved from the case history sheets of the patients. Among  
81 all the cases analyzed, 25 patients who received CSE-1034 as empirical therapy and fulfilled  
82 the other above mentioned inclusion criteria were analyzed further.

83 Different specimens including urine and blood of the patients were tested for the  
84 diagnosis of etiological agent. Various hematological and biochemical investigations  
85 including Hb test, total leukocyte count (TLC), differential leukocyte count (DLC), liver  
86 function test (LFT), kidney function test (KFT) were carried out at the beginning and the end  
87 of treatment to evaluate the clinical progress of the patient and drug efficacy.

## 88 **In-vitro microbial antibiotic-susceptibility testing (AST)**

89 Kirby–Bauer disk diffusion method was used to test the microbial susceptibility of the  
90 antibiotics. Discs for various drugs including pip-taz, CSE-1034, meropenem and colistin  
91 were used and the results were interpreted as per the interpretation criteria of the Clinical and  
92 Laboratory Standards Institute (CLSI) guidelines<sup>18</sup>. Depending on the breakpoints, the  
93 antimicrobial susceptibility of the pathogens involved was classified into susceptible,  
94 intermediate or resistant. Criteria for CSE-0134 was >21mm-S, 14-20-I, ≤13-R.

## 95 **Antibiotic dosage**

96 The dose of CSE-1034 used was 3.0g/12h. The progress of the therapy was evaluated in  
97 terms of improvement in clinical parameters on daily basis and at the end of treatment.

## 98 **Definitions**

99

100 **Clinical success:** The patient's response was considered as clinical success when, the patient  
101 recovered with either first line or 2<sup>nd</sup> line empiric antibiotic therapy.

102 **Clinical failure:** The response was considered as clinical failure when the patient was  
103 switched to other antibiotics or one or more antibiotics are added to the initial regime.

104 **First line antibiotic therapy:** It is defined as the regime started immediately after admission  
105 to the hospital.

106 **Second-line antibiotic therapy:** It is defined as the addition of one or more antibiotics to the  
107 initial regime or a complete or partial replacement of the initial antibiotic with another  
108 parenteral antibiotic regime depending on culture susceptibility results.

109

## 110 **Results**

111

112 Out of 85 patients admitted for cUTI, 38 patients met our inclusion criteria and were  
113 included in this case series study. The characteristics of all the 85 cUTI patients which were  
114 screened and the subgroup patients with diabetes mellitus are presented in Table 1. Of the  
115 total patients screened, 55.3% of the patients consisted of males and 44.7% represented the  
116 female patients. However, in the subgroup of cUTI patients with diabetes mellitus, the male  
117 female ratio was 1:1. Overall, the mean age, systolic pressure, pulse and respiratory rates  
118 were similar in the two groups. However, the average weight and diastolic pressure was  
119 higher in cUTI patients with diabetes mellitus compared to the other group. For other

120 demographic features, refer to Table 1. The most common co-morbidities associated with  
121 cUTI patients which were screened at the time of hospitalization were diabetes mellitus,  
122 hypertension and hepatic disorders. 38 cUTI patients with diabetes mellitus were included in  
123 the final study analysis. In both the categories, *E. coli* was the predominant pathogen isolated  
124 followed by *K. pneumoniae*. Other isolated pathogens at the baseline included *A. baumannii* ,  
125 *P. aeruginosa* and *P. mirabilis*. For further details, refer to Table 1.

126 Anti-microbial susceptibility testing has shown that baseline pathogens isolated from  
127 the patients were multi-drug resistant and were resistant to various classes of drugs including  
128 levofloxacin, gentamicin, ceftriaxone, cefepime and cefazolin. 23.6% (9/38) patients were  
129 reported susceptible to pip-taz, 18.4% (7/38) to cefaperozone-sulbactam, and 63.1% (24/38)  
130 to meropenem. In vitro susceptibility test to CSE-1034 has shown 100% susceptibility to  
131 CSE-1034. The per pathogen antibiotic susceptibility details to various drugs are tabulated in  
132 Table 2.

### 133 **Antibiotic outcome**

134 All the subjects included in this retrospective analysis received CSE-1034 empirically.  
135 Because of the hospital exposure in the last 90 days and prescription of beta-lactams or  
136 BL/BLIs before, CSE-1034 was started empirically in these patients by the concerned  
137 physician.

138 92.1% (35/38) of the patients who received CSE-1034 empiric therapy were observed  
139 to respond positively on the 3<sup>rd</sup> day of treatment and were continued on the same treatment  
140 therapy. These patients showed successful clinical response at the end of therapy and were  
141 completely cured. The average treatment duration in these 35 patients was 11.0 days $\pm$ 2.89  
142 (SD).

143 2 (5.3%) patients who were started empirically with CSE-1034 but were found  
144 resistant after in vitro microbial susceptibility testing, were shifted to meropenem. 1 (2.6%)  
145 patients who showed poor clinical response to CSE-1034 therapy despite being CSE-1034-  
146 susceptible, were also switched to meropenem therapy (Figure 1).

147 After 48h of meropenem treatment, it was observed that all the three patients  
148 responded to the treatment based on the visible improvement in clinical conditions and  
149 laboratory investigations.

150 Overall assessment of the clinical response has shown that CSE-1034 monotherapy  
151 cured 92.1% patients alone. 7.9% patients were cured by meropenem treatment.

152

153 **Discussion**

154 In this study, 44.7% of the patients with cUTI were having diabetes as co-morbidity,  
155 which was comparatively little higher than reported in other Asian countries in various  
156 studies (range 13.0%–24.4%)<sup>19 20 21</sup>. However, in conformity to our observations, a UK-  
157 based observational study in a primary care setting on the incidence of UTIs have reported  
158 60% increase in the risk of UTIs among patients with diabetes ( $n = 135,920$ ) compared to 1:1  
159 matched sample of patients without diabetes<sup>22</sup>. Another retrospective study based in China  
160 has reported the prevalence of UTIs in diabetic patients was 11.2%<sup>23</sup>. The relatively higher  
161 rate in our study could be because both male and female diabetic patients were included in  
162 our study, while the studies based in Asia generally included female diabetic patients. In our  
163 study, prevalence of UTIs in diabetic women was about double compared to diabetic men,  
164 which is related to the characteristics of female urinary tract. Beside the female gender, old  
165 age, BMI and diastolic pressure were also observed as risk factors of UTIs in diabetic  
166 patients; however, systolic pressure, and other demographic features had no relation with  
167 UTIs. The results were in accordance with previous studies<sup>19 23</sup>. The most common  
168 pathogenic microorganisms isolated from UTI patients and cUTI patients with diabetes  
169 mellitus were similar and included *E. coli*, *K. pneumoniae* and *A. baumannii*. The results are  
170 similar to those of other studies<sup>23 24</sup>. He *et al.*<sup>23</sup> and Li *et al.*<sup>25</sup> have reported *E. coli* and *K.*  
171 *pneumoniae* as the most common isolates from cUTI patients alone or with diabetes mellitus.

172 Regarding the antimicrobial resistance profile of uropathogens in the present study, it  
173 was observed that all the isolates were multi-drug resistant, resistant to different classes of  
174 antibiotics including levofloxacin, gentamicin, ceftriaxone, cefepime and cefazolin. Pip-taz or  
175 cefoperozone-sulbactam are the most common choices as 1<sup>st</sup> line of empirical treatment for  
176 patients suspected of hospital acquired infections. As only 18.4-23.6% patients were reported  
177 susceptible to BL-BLIs, thus it makes an inappropriate choice for empirical therapy or 2<sup>nd</sup>  
178 line of empirical treatment for cUTI cases in our hospital. Similar to our observations,  
179 various studies in the past have documented that Gram-negative bacterial infections are  
180 gaining resistance to various anti-microbial drugs including the drug of last resort  
181 carbapenems. The AMR data in India has shown resistance against pip-taz has risen to 65-  
182 70% and about 55-60% against cefoperazone-sulbactam<sup>26</sup>. The indiscriminate prescription of  
183 BL/BLI combinations can be one of the vital reasons for the high AMR reported among the  
184 normally recommended 1st line of treatment for UTIs. AMR data at a tertiary trauma care

185 center of India has reported the resistance against the five classes of antimicrobials as  
186 carbapenems (50%), aminoglycosides (66%), fluoroquinolones (76%), third generation  
187 cephalosporins (88%), BL/BLI combinations (63%) and extra-drug resistance was reported in  
188 27% isolated pathogens<sup>27</sup>. Almost similar to above report, 36.9% were observed susceptible  
189 to meropenem in our study. Increase in carbapenems resistance has been linked with  
190 excessive carbapenem consumption. Hence selection pressure on carbapenems needs to be  
191 reduced either by reducing their consumption by using alternative drugs or developing newer  
192 therapeutic options. There are several publications about use of alternative agents for treating  
193 ESBL infections rather than carbapenems so as to reduce selection pressure without  
194 compromising clinical outcomes<sup>28</sup>.

195 Interestingly, all the patients were reported susceptible to a new combination of drug,  
196 CSE-1034. The higher susceptibility to CSE-1034 could likely be the synergistic effect of the  
197 three components. Disodium edetate, a non-antibiotic adjuvant, present in CSE-1034 chelates  
198 the divalent metal ions leading to membrane destabilization and enhanced penetration of  
199 drugs inside bacterial cells. The Sulbactam component of CSE-1034 is known to have  
200 inherent activity against various bacterial infections. In line with our results, various studies  
201 in the past have also demonstrated higher efficacy of CSE-1034 against various bacterial  
202 infections including UTI<sup>15 17</sup>. Since, CSE-1034 was shown to effectively cure 92.1% of the  
203 patients alone, it can serve as effective choice of treatment for cUTI in diabetic patients.

## 204 **CONCLUSION**

205 Overall, the high carbapenem resistance reported among Gram-negative strains is a matter of  
206 grave concern and needs to be addressed at priority. The antibiotic Adjuvant Therapy scored  
207 over different  $\beta$ -lactam and  $\beta$ -lactamase inhibitor combinations and carbapenems due to its  
208 resistance breaking mechanisms for the treatment of cUTI in diabetic patients.
