THE FUNCTIONAL AND SENSORY EVALUATION OF BISCUITS PRODUCED
FROM WHEAT, DEFATTED SOYBEAN AND COCONUT FLOUR.

ABSTRACT

Aims: The functional and sensory properties of biscuits produced from wheat flour, defatted soybeans and coconut flour were investigated to determine its quality and acceptability.

Study design: The flour blends were formulated as sample A (100% wheat flour), sample B (80% wheat flour + 10% defatted soybean flour + 10% defatted coconut flour), and sample C (60% wheat flour to 20% defatted soybean flour, + 20% defatted coconut flour) respectively.

Place and duration of study: Department of Food Technology, Auchi Polytechnic, Auchi, Edo State; for a duration of 2 months, between August to October, 2014.

Methodology: The biscuit was baked using the straight dough method described by Chuahan et al., (1992). Sensory evaluation was determined according to the methods described by Ihekoronye and Ngoddy, (1985). Physicochemical evaluation was determined by the method described by AOAC (1990).

Results: The result of the sensory analysis recorded sample C as the most acceptable in all the qualities (color, taste, texture and general acceptability). The functional properties recorded sample B as the highest in bulk density with a mean score value of 46.27, while A and C recorded 26.71 and 26.67 respectively. Sample B recorded the highest solubility value at 73.62% while sample A and B recorded 69.14% and 57.24%. Sample C recorded the highest swelling capacity (87.97%), while sample A and B recorded 65.96% and 61.18% respectively. Sample C recorded the highest water absorption capacity (14.38%) while sample A and B recorded 12.37% and 12.60% respectively.

Conclusion: Quality and acceptable wheat biscuits can be produced from wheat flour, defatted soybean flour and defatted coconut flours.

Keywords: Biscuits, wheat flour, defatted soybean flour and coconut flour.

1. INTRODUCTION

Biscuits are nutritive snacks produced from unpalatable dough that is transformed into appetizing product through the application of heat in an oven (1). They are ready to eat, convenient and inexpensive food product, containing digestive and dietary principle of vital importance (2). The principal ingredients are flour, fat sugar and water; while other ingredients include milk, salt, flavoring agent and aerating agent.
Biscuits are a rich source of fat and carbohydrate, hence are energy giving food and they are also a good source of protein and minerals. The use of composite flour in biscuit making has been reported by many researchers. Olaoye et al., (3), investigated the use of the supplementation of flours of soybean and plantain in wheat in the production of biscuit. The research workers were able to obtain acceptable biscuit samples, with up to 15% supplementation of wheat with plantain flour. However, the quality attributes of the products tend to decrease with corresponding increase in the percentage substitution with wheat flour. Notwithstanding, a successful substitution of up to 15% of composite flour in the production of baked products will go a long way in reducing cost and enhancing its utilization. The consumption of biscuit and other western-styled bakery product such as bread and cake prepared from wheat flour has become very popular in Nigeria, especially among children (4). The low protein content of wheat flour is of major concern in its utilization.

Defatted soybeans are obtained from soybeans. They are made from soybean meal that has been dehulled and defatted. Dehulled and defatted soybeans are processed into three kinds of high protein commercial products: soy flour, concentrates, and isolates. Soy protein isolate has been used since 1959 in foods because of its unique functional properties. Recently, the popularity of soy protein has increased due to its uses in health food products, and many countries allow health claims for foods rich in Soy protein.

Defatted soybean is generally regarded as being concentrated in protein bodies, which are estimated to contain at least 60-70% of the total soybean protein. Soybean contains a small but very significant 25 Albumin storage protein. Soybeans can also contain biologically active or metabolic proteins such as enzymes, trypsin inhibitors, hemagglutinins, and cysteine proteases very similar to papain.

Soy beans (Glycine max) a grain legume, is one of the richest and cheapest sources of plants protein that can be used to improve the diet of millions of people especially the poor and low income earners in developing countries because it produces the greatest amount of protein used as food by man. Soybeans can be processed into soy milk, soy sauce, tofu, (soybean curd) soy-yogurt, soy sprouts, soy flour, and many other soy products. Defatted
Soy bean flour can be used for the production of protein isolates and concentrates. Nutritionally, soy bean protein resembles animal protein more closely than other vegetable proteins. Soybean protein constitutes about 40% of the total solids and plays a very important role in the enrichment of cereal baked goods (5). It is also a rich source of vitamin, minerals and is relatively low in crude fiber (6). Soybean is one such protein sources, which when used partially to replace or complement wheat flour in the production of bakery products such as biscuits, bread and other confectionery could go a long way in improving the nutritional status of such products.

Defatted coconut flour is the ground solid residue/flakes obtained after immediate extraction of oil from dried communicated coconut meal that is processed under sanitary conditions. Defatted coconut flour usually have two market values and is normally sold as an animal feed and in some cases, just thrown away (5). Coconut flour is now also being marketed as a functional food, and studies have shown that it has high dietary fiber content that aids in lowering cholesterol and providing other health benefits to the human body. The dietary fiber content of coconut flour and low fat desiccated coconut is much higher than oatmeal and flax seed.

Wheat (*Triticum Spp*) is a grass that is cultivated worldwide. Globally, it is the most important human food grain and ranks second in total production as a cereal crop behind maize, the third being rice. Wheat grain is a staple food used to make flour for leavened, flat and steamed breads, cookies, cakes, pasta, spaghetti, macaroni, noodles, couscous and also for fermentation to make beer, alcohol, vodka or biofuel (4). The husks of the grains are separated and milled to white flour, which is the bran. Wheat is planted to a limited extent as a forage crop for livestock and the straw can be used as fodder for livestock or as a construction material for roofing thatch.

Wheat is considered to be good source of protein minerals, 13-group vitamins and dietary fibre. It is an excellent health-building food (4). Thus, it has become the principal cereal, being more widely used for the making of bread than any other cereal because of the quality and quantity of the characteristic protein called “gluten”. Gluten makes bread dough
stick together and give it the ability to retain gas. The outer bran, which is the much needed roughage, is known to be the indigestible portion that helps easy movement of bowels. The bran, vitamin B, vitamin E and protein of wheat help to build and repair muscular tissues.

2. MATERIALS AND METHODS

The raw materials used were soybeans, coconut, wheat, salt, butter, baking powder, milk and sugar, purchased from Uchi Market of Etsako West Local Government Area, Edo State.

2.1 FORMULATION OF FLOUR BLENDS

The flour samples from wheat, coconut and defatted soybean were mixed at three (3) level combinations as follows:

<table>
<thead>
<tr>
<th>Wheat flour (g)</th>
<th>Defatted soy flour (g)</th>
<th>coconut flour (g)</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>

<td>10</td>
<td>10</td>
</tr>
<tr>
<td>60</td>
<td>20</td>
<td>20</td>
</tr>
</tbody>
</table>

To each of the formulations, the following was added:

- 200g of butter
- 0.1g of sugar
- 5g of baking powder
- 0.25g of salt.

2.1.2 BAKING PROCEDURE

The biscuit was baked using the straight dough method described by Chuahan et al., (1992). The fat and the sugar were mixed thoroughly; until both formed a homogenous mixture (fluffy). All the other ingredients (flour, salt, baking powder and milk) were properly mixed in separate bowls properly. The mixed fat and sugar were added to the ingredients and mixed thoroughly to form dough and kneaded. They were rolled out thinly on a cutting board and cut out into shapes, and placed in a baking pan. The cut dough was transferred to the stove and baked at a temperature of 100°C for 15 minutes. The baked biscuits were allowed to cool at room temperature, and then packaged in an air tight container.

2.2 SENSORY EVALUATION
Twenty five semi-trained panelists were used to carry out the sensory evaluation of the samples using 9 points hedonic scale questionnaire. The panelists were asked to evaluate some of the sensory attributes which include; color, flavor, taste, texture and overall acceptability. They were asked to detect or state their degree of like or dislike.

2.3 PHYSICOCHEMICAL EVALUATION

The water absorption capacity, swelling index, bulk density, oil absorption, gelling point and boiling point were determined by the method described by AOAC (1990).

3 RESULTS AND DISCUSSION

Plates 1, 2, and 3 represents the biscuits produced from wheat flour, defatted coconut flour and defatted soybean flour at different proportions.
Plate 1: BISCUIT PRODUCED FROM 100% WHEAT FLOUR

Plate 2: BISCUIT FROM 80%/10%/10% WHEAT FLOUR/DEFATTED SOYBEAN/DEFATTED COCONUT
Plate 3: BISCUIT FROM 60%/20%/20% WHEAT FLOUR/DEFATTED SOYBEAN/DEFATTED COCONUT

The results of the sensory evaluation of biscuit samples produced from wheat, defatted soybeans and defatted coconut flour are represented in Table 1.

</tbody>
</table>

Means with the same superscripts in the same column are not significantly different (P< 0.05).
Values are means ± standard deviation.
A = 100% wheat flour
B = 80% wheat flour + 10% coconut flour + 10% soybean flour.
C = 60% wheat flour + 20% coconut flour + 20% soybean flour.

The results of the analysis showed that the products were acceptable to consumers. However there was no significant difference (P< 0.05) in the texture of all samples. The mean value for texture in sample C (60% wheat flour / 20% defatted coconut flour/ 20% defatted soybean flour) was higher as compared to other samples. This result indicated that producing biscuit from all the formulations will give products with good textural acceptability as judged by assessors to be above average. Onuh and Abdulsalam (8), made similar observation when “apula” was produced from the inclusion of bambara groundnut in maize flour. For flavor, there was no significant difference (P< 0.05) with the samples. Sample C recorded highest mean value in flavor.

For colour assessment, the mean scores were at a range of 7.53- 8.32. However, sample A and B were not significantly different (P< 0.05) while sample C was significantly different (P< 0.05) from samples A and B. Sample C was rated to have had the best colour quality among the samples. The results of the study also revealed that all the samples were not different significantly (P< 0.05) in taste. However, sample C, was rated highest than other samples taste. General acceptability is assessment parameter used to evaluate products overall qualities. The result indicated that sample C was significantly different (P< 0.05) from samples A and B. These results also indicated that sample C was more acceptable to the consumers in all the parameters assessed.

The results of the functional properties of the sample are represented in table 2. The functional properties showed that the samples were significantly different (P< 0.05) in bulk density. Bulk density is an indication of the porosity of a product which influences packaging design and could be used in determining the type of packaging material required. It is also important in infant feeding where less bulk is desirable (9).

Results of the study recorded significant difference (P< 0.05) in solubility. Solubility was highest in sample B at a mean score value of 73.62%, while sample A and C recorded 69.14% and 57.24% respectively. The samples were significantly different (P< 0.05) in
swelling capacity. Sample C recorded the highest value (87.97%) followed by sample A (65.96%) and sample B recorded the least value (61.18%). The results may be due to the variations of the samples and the processing method adopted. High swelling capacity has been reported as part of the criteria of a good product (10). The results of this study indicated that all the samples were of good quality, since they all had swelling capacity above average. There was significant difference (P< 0.05) in the water absorption capacity of all the samples studied. Sample C recorded the highest water absorption capacity (14.38%), while sample A recorded the lowest water absorption capacity (12.37%). Water absorption capacity is an indication of the extent to which protein can be incorporated into food formulation (9). Increase in water absorption capacity implies high digestibility of the starch. The water absorption capacity represents the ability of a product to associate with water under conditions where water is limiting, in order to improve its handling characteristics and dough making potentials (9);(11).

4 CONCLUSION

Results of this study strongly indicated that quality and acceptable biscuits can be produced from defatted soybeans and defatted coconut flour, up to a substitution level of 40%. However, biscuit samples produced from 20% defatted soybeans and 20% defatted coconut flours were rated as the best in organoleptic quality. In comparison to biscuits produced from whole wheat flour, the functional properties of the biscuits produced from wheat flour substituted with defatted coconut and soybean flour were more enhanced. Thus, whole wheat biscuits fortified with defatted coconut and soybean flour can be regarded as not only organoleptically acceptable, but also of functional benefits.
