

# Synthesis of Mn<sub>3</sub>O<sub>4</sub> Microflowers Anode Material for Lithium-ion Batteries with Enhanced Performance

## ABSTRACT

It is important to prepare novel micro-nanostructures of Mn oxides for energy storage. A simple and versatile method for preparation of Mn<sub>3</sub>O<sub>4</sub> microflowers associated with super-thin nanosheets is developed via a solvo-thermal approach, which are tested as a new high-capacity anode material for lithium-ion batteries. Mn<sub>3</sub>O<sub>4</sub> microflowers show better cycling performance than Mn<sub>3</sub>O<sub>4</sub> nanoparticles. Research on this topic mainly sheds some light on the preparation of three-dimensional flower-like oxide hierarchical architectures with improved electrochemical performance for energy storage.

*Keywords: Manganese oxide; Hierarchical architectures; Anode; Lithium-ion battery; Surfactant; Nanosheet.*

## 1. INTRODUCTION

Rechargeable batteries with reversible and efficient electrochemical energy storage and conversion are urgent in various applications, such as portable electronic consumer devices, electric vehicles, and large-scale electricity storage in smart and intelligent grids as renewable and clean energy [1, 2]. Lithium-ion battery is one of the fascinating rechargeable batteries for high energy density coupled with a long life cycle and charge-discharge rate capability [3]. Studies have been conducted to develop low-cost, sustainable, renewable, safe, and high-energy density electrode materials for lithium-ion batteries. Considering environmental safety, researchers should prepare potential electrode materials for lithium-ion batteries through green chemistry based on simple and inexpensive procedures.

Manganese based anode materials are less toxic, abundant in natural resources [4]. Though Mn<sub>3</sub>O<sub>4</sub> is isostructural with Co<sub>3</sub>O<sub>4</sub>, it has poor lithiation activity and electrically insulating, resulting in fast capacity decay as anode materials for lithium-ion batteries. Recently great progress has been achieved for Mn<sub>3</sub>O<sub>4</sub> anode materials. The improved electrochemical properties turned true via the following methods. Mesoporous carbon, graphene, carbon nanotube and various carbon nanostructures were introduced to prepare carbon based Mn<sub>3</sub>O<sub>4</sub> nano-composites. These composites showed better cycling stability and higher discharge capacity than bulk Mn<sub>3</sub>O<sub>4</sub> for fast ion diffusion, good electronic conductivity, and skeleton supporting function [5-35]. People also designed various Mn<sub>3</sub>O<sub>4</sub> nanostructures to improve the cycling performance of Mn<sub>3</sub>O<sub>4</sub>. In these Mn<sub>3</sub>O<sub>4</sub> nanostructures, well-shaped nanostructure, pore, hollow structure and 3D array played an important role in the long cycling performance. Novel pongelike nanosized Mn<sub>3</sub>O<sub>4</sub> exhibits a high initial reversible capacity of 869 mA h g<sup>-1</sup> and significantly enhanced first coulomb efficiency with a stabilized reversible capacity of around 800 mA h g<sup>-1</sup> after over 40 charge/discharge cycles [4]. Mn<sub>3</sub>O<sub>4</sub> hollow microspheres demonstrate a good electrochemical performance, with a high reversible capacity of 646.9 mA h g<sup>-1</sup> after 240 cycles at a current density of 200 mA h g<sup>-1</sup> [36]. While while fluorinated Mn<sub>3</sub>O<sub>4</sub> nanospheres for lithium-ion batteries show poor cycling performances [37]. 3D porous Mn<sub>3</sub>O<sub>4</sub> nanosheet arrays could be directly used as a binder-free and conductive-agent-free electrode to deliver ultrahigh electrochemical performance [38]. It is reported that the 3D pores and voids between the nanosheet arrays could provide rapid ion transfer channels, as well as accommodating the volumetric changes of Mn<sub>3</sub>O<sub>4</sub> during the electrochemical cycling [38]. The ultrathin Mn<sub>3</sub>O<sub>4</sub> nanosheets exhibit a high reversible capacity and stronger cycling stability for high surface area [39]. The well-shaped Mn<sub>3</sub>O<sub>4</sub> tetragonal bipyramids with high-energy facets show a high initial discharge capacity. In addition, the anode displays a good fast rate performance and delivers a reversible capacity of 822.3 mA h g<sup>-1</sup> (the theoretical capacity: 937 mA h g<sup>-1</sup> at a current density of 0.2 C after 50 cycles [40]). The porous Mn<sub>3</sub>O<sub>4</sub> nanorods can improve electrochemical reaction kinetics and favor the formation of Mn<sub>3</sub>O<sub>4</sub> [41]. Mn<sub>3</sub>O<sub>4</sub> nano-octahedra has a discharge capacity of 667.9 mA h g<sup>-1</sup> after 1000 cycles at

48 1.0  $\text{A g}^{-1}$  ascribed to the lower charge transfer resistance due to the exposed highly active {011}  
49 facets, which can facilitate the conversion reaction of  $\text{Mn}_3\text{O}_4$  and Li owing to the alternating Mn and O  
50 atom layers, resulting in easy formation and decomposition of the amorphous  $\text{Li}_2\text{O}$  and the multi-  
51 electron reaction [42]. The hollow  $\text{Mn}_3\text{O}_4$  spheres deliver a highly stable cycle performance with  
52 capacity retention of similar to  $980 \text{ mA h g}^{-1}$  for over 140 cycles at  $200 \text{ mA g}^{-1}$  and an excellent rate  
53 capability [43]. It can be seen that  $\text{Mn}_3\text{O}_4$  with nanosheets, pore, high surface area and  
54 interconnected voids are apt to show high discharge capacity and long cycling stability. The 3D  
55 assembling  $\text{Mn}_3\text{O}_4$  microflowers assembling with nanosheets are expected to show favorable  
56 electrochemical performances for the presence of voids among the nanosheet arrays. There are few  
57 reports on the research of  $\text{Mn}_3\text{O}_4$  microflowers except  $\text{Mn}_3\text{O}_4\text{-Fe}_3\text{O}_4$  and  $\text{MnO-Mn}_3\text{O}_4$  nanoflowers.  
58  $\text{Mn}_3\text{O}_4\text{-Fe}_3\text{O}_4$  nanoflowers are simply fabricated through one step etching  $\text{Mn}_5\text{Fe}_5\text{Al}_{90}$  ternary alloy,  
59 which exhibits higher performance as anode material for lithium ion batteries than that of pure  $\text{Mn}_3\text{O}_4$   
60 and  $\text{Mn}_3\text{O}_4$  anodes for unique hierarchical flower-like structure and the synergistic effects between  
61  $\text{Mn}_3\text{O}_4$  and  $\text{Mn}_3\text{O}_4$  [44]. A hierarchically porous  $\text{MnO-Mn}_3\text{O}_4$  nano-flowers can be fabricated by  
62 dealloying Mn/Al alloys in aqueous NaOH solution in the presence of  $\text{H}_2\text{O}_2$ , and upon annealing,  
63 which has a capacity of 1018, 901 and  $757 \text{ mA h g}^{-1}$  with nearly 100% retention capacity after 100  
64 cycles at 100, 200 and  $500 \text{ mA g}^{-1}$  [45].  $\text{Mn}_3\text{O}_4$  nanosheets associated with nanorods can be  
65 assembled to 3D flower-like  $\text{Mn}_3\text{O}_4$  with hexadecyl trimethyl ammonium bromide (CTABr), urea and  
66  $\text{MnSO}_4$  as reagents, while they did not tested any properties, e.g. batteries [46].

67 In this study, a simple method was developed to prepare  $\text{Mn}_3\text{O}_4$  microflowers associated with  
68 nanosheets. These microflowers were synthesized in a N,N-dimethylformamide (DMF)-water solution  
69 with the aid of CTABr. When tested as an anode material for lithium-ion batteries, the  $\text{Mn}_3\text{O}_4$   
70 microflowers exhibited enhanced cycling stability than  $\text{Mn}_3\text{O}_4$  nanoparticles.

## 71 2. MATERIAL AND METHODS / EXPERIMENTAL DETAILS / METHODOLOGY (ARIAL, 72 BOLD, 11 FONT, LEFT ALIGNED, CAPS) 73 74

75 All chemicals are commercially available. The preparation was performed via a solvothermal method  
76 in a DMF-water mixed solvent. In a typical procedure, 1 mmol manganese acetate tetrahydrate and  
77 0.5 g hexadecyl trimethyl ammonium bromide (CTABr) were added to a 5 ml DMF- 25 ml water  
78 solution and stirred at room temperature for 2 hours. After that, the mixture was transferred to a 50-ml  
79 Teflon-lined stainless autoclave, sealed, kept at  $200 \text{ }^\circ\text{C}$  for 24 hours, cooled to room temperature,  
80 washed with absolute alcohol and dried at  $70 \text{ }^\circ\text{C}$  for 12 hours (marked with DT-1). Sample DT-2 was  
81 prepared without CTABr under the identical condition. While Sample DT-3 was prepared with 30 ml  
82 water in the absence of CTABr.

83 The morphological characteristics of the as-synthesized materials were observed with a Hitachi S-  
84 4800 field emission scanning electron microscope (SEM). X-ray diffraction (XRD) patterns were  
85 recorded on a diffract meter (Co  $\text{K}\alpha$ , Analytical, and Pert). Cyclic voltammetry (CV) experiments were  
86 performed with a Chi660c electrochemical workstation at a scan rate of  $1 \text{ mV S}^{-1}$ . A Land CT2001A  
87 battery tester was used to measure the electrode activities at room temperature.

88 The as-synthesized samples were tested as anode materials for lithium-ion batteries. The composite  
89 of negative electrode material was consisted of the active material, a conductive material (super-pure  
90 carbon) and binder polyvinylidene difluoride (PVDF) in a weight ratio of 7/2/1. The Li metal was used  
91 as the counter electrode. The cells were charged and discharged between a 0.05 - 3.0 V voltage limit.  
92

## 93 3. RESULTS AND DISCUSSION 94

95 Three samples were obtained by adjusting synthesis parameters. Both DMF and CTABr play an  
96 important role in the formation of different morphologies. When water was used as the solvent in the  
97 absence of CTABr, the sample appears as monodispersed nanoparticles between 30 and 150 nm in  
98 Fig. 1a,b. While DMF was added, thin microplatelets were obtained, as shown in Fig. 1c, d. The  
99 length and width of microplatelets can be up to several  $\mu\text{m}$ . There are also some thin nanobelts.  
100 Some microflowers composed of superimposed thin and wide nanosheets were prepared with CTABr  
101 in the DMF- $\text{H}_2\text{O}$  mixed solvent in Fig. 1e, f. Certain microflower is several  $\mu\text{m}$  in size.  
102

103 X-ray diffraction was performed to identify the structure of the three samples. It can be seen that  
104 CTABr plays an important role in the crystallization of products. The diffraction peaks of the sample  
105 prepared with DMF, water and CTABr has the highest intensity than samples prepared with water,  
106 CTABr and DMF in Fig. 2. The diffraction peaks can be ascribed to  $Mn_3O_4$  in Fig. 2a (JCPDS 89-  
107 4837). The other samples can also be ascribed to  $Mn_3O_4$  in Fig. 2b,c, respectively. All the  $Mn_3O_4$   
108 here are lack of the peak of (101), which means that the is not the high-energy {101} plane.

109  
110 The electrochemical performance of  $Mn_3O_4$  nanoparticles and microflowers was evaluated as anode  
111 materials for lithium-ion batteries (Fig. 3). Fig. 3a shows the 1<sup>st</sup> and 2<sup>nd</sup> charge-discharge profiles of  
112  $Mn_3O_4$  microflowers at a current density of 240  $mA\ g^{-1}$  (Sample T-72). A long discharge platform is  
113 observed at 0.5 V in the first discharge curve, but this platform disappears in the succeeding  
114 discharge curves. The  $Mn_3O_4$  microflowers-based composite electrode delivers an initial discharge  
115 capacity of 1496  $mA\ h\ g^{-1}$ . However, the 1<sup>st</sup> discharge profiles of  $Mn_3O_4$  nanoparticles show four  
116 discharge platforms at 0.33, 0.44, 0.92 and 1.3 V, implying that a multi-step conversion reaction takes  
117 place. A new platform at 0.7 V appears in the succeeding discharge curves. The  $Mn_3O_4$   
118 nanoparticles-based composite electrode delivers an initial discharge capacity of 1280  $mA\ h\ g^{-1}$ . It  
119 can be seen that  $Mn_3O_4$  without high-energy {101} plane can also have a very high initial discharge  
120 capacity. It can also be found that  $Mn_3O_4$  nanoparticles have a steeper charge curve than  $Mn_3O_4$   
121 microflowers between 1.4 and 3.0 V implying that a severe polarization takes place in the  $Mn_3O_4$   
122 nanoparticles-based composite electrode.

123  
124 We also performed the  $dQ/dV$ -V curves obtained from the 1<sup>st</sup> and 2<sup>nd</sup> charge-discharge curves of  
125  $Mn_3O_4$  nanoparticles and microflowers in Fig. 4. In the first charge-discharge cycle of  $Mn_3O_4$   
126 nanoparticles, four reduction peaks are centered at 0.33, 0.45, 0.90 and 1.3 V, and the oxidation peak  
127 is at 1.24 V in Fig. 4a. In the first charge-discharge cycle of  $Mn_3O_4$  microflowers, the reduction and  
128 oxidation peaks are centered at 0.33 and 1.28 V in Fig. 4b, respectively. In the second charge-  
129 discharge cycle of  $Mn_3O_4$  nanoparticles, two reduction peaks are centered at 0.45 and 0.52 V, and the  
130 oxidation peak is at 1.24 V in Fig. 5b. In the second charge-discharge cycle of  $Mn_3O_4$  microflowers,  
131 the reduction and oxidation peaks are centered at 0.54 and 1.25 V in Fig. 2, respectively. The  
132 reduction peaks in the range of 1.3-0.4 V was ascribed to reduction from Mn(III) to Mn(II), and the 0.4-  
133 0.1 V range reflected the reduction from Mn(II) to Mn(0) [47,48]. The difference of first discharge curve  
134 between  $Mn_3O_4$  microflowers and nanoparticles is because  $Mn_3O_4$  microflowers only undergoes the  
135 reduction from Mn(II) to Mn(0). While  $Mn_3O_4$  nanoparticles undergo reductions from Mn(III) to Mn(II) to  
136 Mn(0). In the second discharge process, in the second discharge, the contribution to discharge  
137 capacity is mainly ascribed to the reduction around 0.5 V. The Li<sup>+</sup> charge reaction: is  $Mn_3O_4 + 8Li^+ +$   
138  $8e^-$  to  $3Mn(0) + 8Li_2O$  [49]. Compared to  $Mn_3O_4$  nanoparticles,  $Mn_3O_4$  microflowers does not undergo  
139 reduction from Mn(III) to Mn(II) and reduce polarization.

140  
141 Fig.6 is the cycling performance testes at current densities of 240 and 480  $mA\ g^{-1}$ . The  $Mn_3O_4$   
142 microflowers-based composite electrode delivers a second discharge capacity of 870.2 and 714.8  
143  $mA\ h\ g^{-1}$  in Fig. 6a,b, respectively. A reversible capacity of 392.8 and 358.5  $mA\ h\ g^{-1}$  is retained after  
144 20 cycles. The  $Mn_3O_4$  nanoparticles-based composite electrode show lower discharge capacity and  
145 worse cycling stability at current densities of 240 and 480  $mA\ g^{-1}$  in Fig. 6c,d. It delivers a second  
146 discharge capacity of 332.8 and 156.5  $mA\ h\ g^{-1}$ , respectively. The final discharge capacity is even low  
147 to 131.3 and 53.8  $mA\ h\ g^{-1}$ . The fast capacity decay of  $Mn_3O_4$  nanoparticles is due to the reduction  
148 from Mn(III) to Mn(II). The improved electrochemical performance of  $Mn_3O_4$  microflowers is due to  
149 reduce the activity of  $Mn_3O_4$ , avoid the complicated reduction from Mn(III) to Mn(II) and reduce  
150 polarization. We have focused on the research of flower-like rutile  $TiO_2$  and ammonium vanadium  
151 bronze. We found that the effect of flower-like nanostructures on the reaction kinetics of the electrode  
152 are ascribe to the changes the total impedance and electron transfer resistance [50, 51]. The improved  
153 performance of  $Mn_3O_4$  micro-flowers is also ascribed to improve the transferring of electron.

Comment [M1]: Text mentions Fig 5.b but Fig 5.a has not been mentioned.

Comment [M2]:

Comment [M3R2]: Repeated.

Comment [M4]: Seems to be an equation reaction. If this is the case, normally an arrow ( $\rightarrow$ ) is used to separate reagents from products of reaction.

#### 4. CONCLUSION

In summary,  $\text{Mn}_3\text{O}_4$  microflowers associated with super-thin nanosheets were prepared by using a solvo-thermal method with the aid of surfactant CTABr. The  $\text{Mn}_3\text{O}_4$  microflowers exhibit better cycling stability and higher discharge capacity than  $\text{Mn}_3\text{O}_4$  nanoparticles as anode materials for lithium-ion batteries due to reduce the activity of  $\text{Mn}_3\text{O}_4$ , -avoid the complicated reduction from Mn(III) to Mn(II) and reduce polarization. This simple method may also be used to fabricate other anode materials for lithium-ion batteries with improved electrochemical performance.

**Comment [M5]:** Conclusions should explore more the results obtained to really show the good work done by the author. A language review would make paper more clear and improve its quality.
